

Form for the Diagnosis of Death using Neurological Criteria in Children 2 months to 18 years* {long version}

* midnight the day prior to the 18th birthday

This form is consistent with and should be used in conjunction with, the AoMRC (2008) A Code of Practice for the Diagnosis and Confirmation of Death¹ and has been endorsed for use by the following institutions: Faculty of Intensive Care Medicine, Intensive Care Society, Paediatric Intensive Care Society, Royal College of Paediatrics and Child Health and National Organ Donation Committee: Paediatric Subgroup. Date for review: 1/5/2023

Number HOSPITAL ADDRESSOGRAPH or

Surname

First Name

Date of Birth

NHS/CHI number

Objective of Care

- To diagnose and confirm the death of a mechanically ventilated, severely brain injured patient in coma, using neurological criteria.

Academy of the Medical Royal Colleges Definition of Human Death (2008)¹

"Death entails the irreversible loss of those essential characteristics which are necessary to the existence of a living human person and, thus, the definition of death should be regarded as the irreversible loss of the capacity for consciousness, combined with irreversible loss of the capacity to breathe. The irreversible cessation of brain-stem function whether induced by intra-cranial events or the result of extra-cranial phenomena, such as hypoxia, will produce this clinical state and therefore irreversible cessation of the integrative function of the brain-stem equates with the death of the individual and allows the medical practitioner to diagnose death."

Context

- National professional guidance advocates the confirmation of death by neurological criteria wherever this seems a likely diagnosis and regardless of the likelihood of organ donation.^{3,4,7}
- UK General Medical Council (GMC) guidance on end of life care (2010) states that national procedures for identifying potential organ donors should be followed and, in appropriate cases, the specialist nurse for organ donation (SN-OD) should be notified. NICE guidance and UKPICS Standards recommend that the specialist nurse for organ donation (SN-OD) should be notified at the point when the clinical team declare the intention to perform brain-stem death tests.^{2,3,4}

Date and time of referral to SN-OD:

- Whilst most patients will already be in an Intensive Care Unit (ICU) when the diagnosis is suspected, some patients may be in other areas, e.g. the Emergency Department. On such occasions, it is legitimate, if considered necessary, to transfer a patient to the ICU for the diagnosis to be made.
- For many clinicians, the diagnosis and confirmation of death using neurological criteria, will be a relatively infrequent task and may be complicated by uncertainties regarding the nature of the primary diagnosis, irreversibility and the availability of suitably experienced personnel. Updated guidance on the diagnosis and confirmation of death by neurological criteria was published by the Academy of the Medical Royal Colleges (AoMRC) in 2008. ¹ For infants from 37 weeks to < 2 months guidance was published by the Royal College of Paediatric and Child Health in 2015. ⁶

The person with parental responsibility for the child and other close family members should be made aware that the purpose of testing is to confirm the child's death. If given an opportunity to witness the neurological examination, they should be appropriately supported and prepared for the possibility of spinal reflexes and their lack of relevance, as far as the diagnosis of death by neurological criteria is concerned. Whether the child's close family witness the clinical examination or not, the child's need for dignity and privacy, should remain paramount.

Form for the Diagnosis of Death using Neurological Criteria in Children 2 months to 18 years {full guidance version}

* midnight the day prior to the 18th birthday

Patient Name:.....DOB:..... NHS/CHI Number:.....

Preparation

1. Evidence for Irreversible Brain Damage of known Aetiology

Case records, past medical history including possibly contacting the GP, relevant imaging.

2. Exclusion of Reversible Causes of Coma and Apnoea

Standard ICU cardio-respiratory monitoring (to ensure haemodynamic stability), medication chart and history, blood and urine drug assay results (where relevant), drug antagonists (e.g. flumazenil, naloxone), peripheral nerve stimulator, recent serum glucose and biochemistry, thermometer, patient warming device.

3. Tests for Absence of Brain-Stem Function

Brain-stem reflexes: Bright light source; small sterile gauze swabs, otoscope with disposable ear pieces, 20 or 50 ml luer lock syringe and disposable quill, ice-cold water; a spatula, Yankauer sucker or laryngoscope, endotracheal suction catheters.

Apnoea test: Haemodynamic monitoring (continuous ECG, invasive arterial pressure), arterial blood gas analysis including blood gas syringes x 4, pulse oximetry and end-tidal CO₂ monitoring, means of delivering oxygen to the trachea by bulk flow (i.e. using a circuit which maintains oxygenation and CPAP e.g. Mapleson C, Ayres T piece, or endotracheal suction catheter and oxygen tubing).

Diagnostic caution is advised in the following 'Red Flag' patient groups. (Based on the literature and unpublished case reports.) For advice in difficult circumstances contact the local or regional Clinical Lead for Organ Donation or the regional paediatric intensive care units.

- | | | |
|--|---|---|
| 1. Testing < 6 hours of the loss of the last brain-stem reflex | 4. Patients with any neuro-muscular disorders | 6. Prolonged fantanyl infusions |
| 2. Testing < 24 hours from the loss of last brain stem reflex where aetiology primarily anoxic damage | 5. Steroids given in space occupying lesions such as abscesses | 7. Aetiology primarily located to the brain-stem or posterior fossa |
| 3. Hypothermia (24-hour observation period following re-warming to normothermia recommended) | | |

Examining Doctors

Date and time:

Doctor One, Name and Designation

Name:

Grade:

Patient Location

Doctor Two, Name and Designation

Name:

Grade:

Guidance

- The diagnosis of death by neurological criteria should be made by at least two medical practitioners. Both medical practitioners should have been registered with the General Medical Council (or equivalent Professional Body) for more than five years and be competent in the assessment of a patient who may be deceased following the irreversible cessation of brain-stem function and competent in the conduct and interpretation of the brain-stem examination. In infants, children and young adolescents it is recommended that one of the doctors should be a consultant, one of them should normally be a paediatrician or should have experience with children and one of them should not be primarily involved in the child's care. Those carrying out the tests must not have, or be perceived to have, any clinical conflict of interest and neither doctor should be a member of the transplant team. Clinical Leads for Organ Donation can carry out testing and are likely to have significant expertise.
- Testing should be undertaken by the nominated doctors acting together and must always be performed on two occasions. A complete set of tests should be performed on each occasion, i.e., a total of two sets of tests will be performed. Doctor One may perform the tests while Doctor

* midnight the day prior to the 18th birthday

Patient Name:.....DOB:..... NHS/CHI Number:.....

Two observes; this would constitute the first set. Roles may be reversed for the second set. The tests, in particular the apnoea test, are therefore performed only twice in total.

Evidence for Irreversible Brain Damage of known Aetiology

Diagnosis:

Evidence for Irreversible Brain Damage of known Aetiology:

Guidance

1. The patient must have a Glasgow Coma Scale score of 3 and be mechanically ventilated with apnoea.
2. There should be no doubt that the patient's condition is due to irreversible brain damage of known aetiology.
3. It remains the duty of the two doctors carrying out the testing to be satisfied with the aetiology, the exclusion of all potentially reversible causes, the clinical tests of brain-stem function and of any ancillary investigations (see page 8); so that each doctor may independently confirm death following irreversible cessation of brain-stem function.
4. Occasionally it may take a period of continued clinical observation and investigation to be confident of the irreversible nature of the brain injury. The timing of the first test and the timing between the two tests should be adequate for the reassurance of all those directly concerned.
5. It is recommended that there is a minimum of twenty-four hours, of continued clinical observation, in patients where anoxic damage, following cardiorespiratory arrest, is the aetiology of the brain injury. If prior treatment of the patient has included induced hypothermia, it is recommended that there is a minimum of twenty-four hours, of continued clinical observation, following re-warming to normothermia. See above for 'Red Flag' patient groups.
6. Stabilisation of the patient prior to testing, especially support of the cardiovascular system, is a prerequisite to testing. Mean blood pressure should be consistently maintained at age appropriate levels (see appendix 1)⁵ and appropriate fluid resuscitation administered. This almost invariably requires the use of inotropes / vasopressors via central venous access.
7. Diabetes insipidus can develop rapidly and should be suspected in patients with a high urine output (typically > 4 ml/kg/hr) and rising serum sodium concentration. Matched urinary and plasma electrolytes and osmolality may assist in the diagnosis. Treatment with desmopressin; 2 month - 12 years 400 nanograms, 12 - 18 years 1 - 4 micrograms IV boluses, is usually sufficient for treatment but repeated doses or vasopressin infusion may be required. Plasma sodium should ideally be maintained within normal limits.

Exclusion of Reversible Causes of Coma and Apnoea

Guidance

Attempts should be made to maintain relatively normal cardiovascular and respiratory physiological parameters in the preceding hours prior to testing. *This may not be possible and does not necessarily preclude testing.*

The key question the two doctors must exclude is the possibility that cardiovascular and respiratory instability is the cause of the observed coma and apnoea.

The answer should be no.

Suggested cardiovascular goals for children:

- Sinus rhythm 60 - 170 beats per minute, as age appropriate (see appendix 1)⁵

Form for the Diagnosis of Death using Neurological Criteria in Children 2 months to 18 years {full guidance version}

* midnight the day prior to the 18th birthday

Patient Name:.....DOB:..... NHS/CHI Number:.....

- Mean arterial pressure 44 - 111 mmHg, as age appropriate (see appendix 1)⁵

	1 st Test		2 nd Test	
Mean arterial pressure at time of testing? Should be consistently maintained at age appropriate levels prior to testing.	mmHg		mmHg	
PaCO₂ at time of testing? A goal of normocarbica (PaCO ₂ <6.0 kPa), <i>if possible</i> , is recommended in the hours prior to testing. See below for <i>starting PaCO₂ in the apnoea test</i> .	kPa		kPa	
PaO₂ at time of testing? Hypoxia should be avoided (PaO ₂ >10 kPa). For infants/children with congenital cyanotic heart disease oxygen levels should be kept in their normal range	kPa		kPa	
Arterial pH/[H⁺] at time of testing? Acidaemia and alkalaemia should be avoided, <i>if possible</i> , aiming for a relatively normal pH 7.35 - 7.45 / [H ⁺] 45 - 35 nmol/L.	pH/[H ⁺]=		pH/[H ⁺]=	
Is the coma or apnoea due to ongoing cardio-respiratory instability? (To diagnose death using neurological criteria, ALL answers should be NO)	Dr One Yes / No	Dr Two Yes / No	Dr One Yes / No	Dr Two Yes / No

Guidance

- The patient should not be receiving any drugs that might be contributing to the unconsciousness, apnoea and loss of brain-stem reflexes (narcotics, hypnotics, sedatives or tranquillisers); nor should they have any residual effect from any neuromuscular blocking agents (atracurium, vecuronium or suxamethonium).
 - It remains the duty of the two doctors carrying out the testing to be satisfied that sufficient time has elapsed to ensure that any remaining drug effect is non-contributory to the unconsciousness and loss of brain-stem reflexes. This will be based on an assessment of the medications the patient has received and from knowledge of the pharmacokinetics of these agents. Renal or hepatic failure and immaturity in younger children may prolong metabolism / excretion of these drugs. See above for 'Red Flag' patient groups.
 - Serum Na⁺ levels below 115 or above 160mmol/l are associated with unresponsiveness. This should be borne in mind if the primary cause of unresponsiveness is uncertain. Testing for DNC should not be carried out if serum K⁺ <2 mmol/L, or serum PO₄³⁻ and/or Mg²⁺ < 0.5 mmol/L or > 3.0 mmol/L as there may be associated severe neuromuscular weakness.
 - Blood glucose should be between 3.0 - 20mmol/L before each brain-stem test.
- If there is any clinical reason to expect endocrine disturbances, then it is obligatory to ensure appropriate hormonal assays are undertaken.

	1 st Test	2 nd Test
Where there is any doubt, specific drug levels should be measured (Testing for DNC should not be carried out if midazolam level is > 10mcg/L, or thiopentone level is > 5mg/L)	Drug levels (if measured):	Drug levels (if measured):

* midnight the day prior to the 18th birthday

Patient Name:.....DOB:..... NHS/CHI Number:.....

Antagonists such as flumazenil, naloxone and neostigmine may be used but there is no specific pharmacological data for predicting the dose effect of these antagonists.	Drug antagonists (if used):	Drug antagonists (if used):		
Residual neuromuscular blockade can be tested for, if necessary, by peripheral nerve stimulation.	Train of Four (if measured):	Train of Four (if measured):		
Is the coma or apnoea due to depressant drugs? (To diagnose death using neurological criteria, ALL answers should be NO)	Dr One Yes / No	Dr Two Yes / No	Dr One Yes / No	Dr Two Yes / No
Body temperature at time of testing? If core temperature is $\leq 34^{\circ}\text{C}$ testing cannot be carried out.	$^{\circ}\text{C}$		$^{\circ}\text{C}$	
Serum sodium (Na^+) at time of testing? Serum sodium should not be < 115 or > 160 mmol/L. Rapid rises or falls in Na^+ should be avoided.	mmol/L		mmol/L	
Serum potassium (K^+) at time of testing? Serum potassium should be > 2 mmol/L	mmol/L		mmol/L	
Serum phosphate (PO_4^{3-}) at time of testing? Serum phosphate should not be profoundly elevated (> 3.0 mmol/L) or lowered (< 0.5 mmol/L) from normal.	mmol/L		mmol/L	
Serum magnesium (Mg^{2+}) at time of testing? Serum magnesium should not be profoundly elevated (> 3.0 mmol/L) or lowered (< 0.5 mmol/L) from normal.	mmol/L		mmol/L	
Blood glucose at time of testing? Blood glucose should be between 3.0 - 20.0 mmol/L and should be tested prior to each test.	mmol/L		mmol/L	
If there is any clinical reason to expect endocrine disturbances hormonal assays should be undertaken.	Hormone level (if measured):		Hormone level (if measured):	
Is the coma or apnoea due to a metabolic or endocrine disorder? (To diagnose death using neurological criteria, ALL answers should be NO)	Dr One Yes / No	Dr Two Yes / No	Dr One Yes / No	Dr Two Yes / No

Guidance

It remains the duty of the two doctors carrying out the testing to be satisfied that the only explanation for the respiratory failure is due to the irreversible cessation of brain-stem function. A train of four examination, using a peripheral nerve stimulator, may be required. See above for 'Red Flag' patient groups.

Tests for Absence of Brain-Stem Function

Preparation for the Apnoea Test

- Oxygenation and cardiovascular stability should be maintained through each apnoea test. Pre-oxygenate FiO₂ 1.0.
- Allow PaCO₂ to rise to at least 6.0 kPa by reducing the minute ventilation prior to commencing the apnoea test. End tidal carbon dioxide can be used to guide the starting of each apnoea test but should not replace the pre and post arterial PaCO₂.
- Cardiac pulsation may be sufficient to trigger supportive breaths if the patient remains connected to the mechanical ventilator and on a spontaneous breathing mode. Performing the apnoea test whilst remaining on mechanical ventilation is not recommended.

Guidance:

It is important to maintain oxygenation above 85% and cardiovascular stability.

Recommended methods:

- CPAP circuit (e.g. Mapleson C or Ayres T piece), especially if oxygenation is a problem, or
- Disconnect the patient from the ventilator and administer oxygen via a catheter in the trachea at a rate of 2 - 6L/minute. Ensure oxygen catheter does not occlude ETT.
- Considerable atelectasis develops in the apnoeic period. At the conclusion of the apnoea test, manual recruitment manoeuvres should be carried out before resuming mechanical ventilation.

	1 st Test	2 nd Test		
Arterial Blood Gas PRE-apnoea test: Confirm PaCO ₂ is at least 6.0 kPa but not substantially greater. In patients with chronic CO ₂ retention, or those who have received intravenous bicarbonate, it is recommended that PaCO ₂ is allowed to rise to above 6.5 kPa.	1 st Test Starting PaCO ₂ : <div style="text-align: right;">kPa</div> Should be ≥6.0 kPa	2 nd Test Starting PaCO ₂ : <div style="text-align: right;">kPa</div> Should be ≥6.0 kPa		
PRE-Arterial Blood Gas pH: Confirm pH < 7.4	pH = Should be <7.4	pH = Should be <7.4		
Start time: Time when apnoea test was commenced.	hr : min (24 hour clock)	hr : min (24 hour clock)		
Arterial Blood Gas POST apnoea test: Ensure the PaCO ₂ has increased by greater than 0.5 kPa.	1 st Test Stopping PaCO ₂ : <div style="text-align: right;">kPa</div> Should have increased by >0.5 kPa	2 nd Test Stopping PaCO ₂ : <div style="text-align: right;">kPa</div> Should have increased by >0.5 kPa		
Stop time: Time when apnoea test was ceased.	hr : min (24 hour clock) <i>Perform lung recruitment</i>	hr : min (24 hour clock) <i>Perform lung recruitment</i>		
Was there any spontaneous respiration during a minimum of 5 (five) minutes continuous	Dr One Yes	Dr Two Yes	Dr One Yes	Dr Two Yes

observation following disconnection from the ventilator? (To diagnose death using neurological criteria, ALL answers should be NO)	/ No	/ No	/ No	/ No
--	------	------	------	------

Ancillary Investigations Used to Confirm the Diagnosis

Guidance:

Ancillary investigations are **NOT** required for the diagnosis and confirmation of death using neurological criteria.

They may be useful however, where neurological examination is not possible (e.g. extensive facio-maxillary injuries, residual sedation and some cases of paediatric hypoxic brain injury), where a primary metabolic or pharmacological derangement cannot be ruled out or in cases of high cervical cord injury, or where spontaneous or reflex movements in the patient generate uncertainty over the diagnosis. In such cases a confirmatory test may reduce any element of uncertainty and possibly foreshorten any period of observation prior to formal testing of brain-stem reflexes. Any ancillary or confirmatory investigation should be considered **ADDITIONAL** to the fullest clinical testing and examination (as outlined above) carried out to the best of the two doctors' capabilities in the given circumstances.

The utility of any additional investigation is for the two testing doctors to decide and they should seek further professional opinion from other specialities and other expert centres, where appropriate. Some possible ancillary investigations are:

- Neurophysiological demonstration of loss of bioelectrical activity in the brain (EEG, evoked potentials).
- Radiological demonstration of absent cerebral blood flow or brain tissue perfusion (CT angiography, 4 vessel angiography, transcranial doppler).

The interpretation of ancillary investigations is complex and their availability usually restricted to neurological centres.
